Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.
An Overview of Severe Acute Respiratory Syndrome-Coronavirus (SARS-CoV) 3CL Protease Inhibitors: Peptidomimetics and Small Molecule Chemotherapy

Abstract

Severe acute respiratory syndrome (SARS) is caused by a newly emerged coronavirus that infected more than 8000 individuals and resulted in more than 800 (10-15%) fatalities in 2003. The causative agent of SARS has been identified as a novel human coronavirus (SARS-CoV), and its viral protease, SARS-CoV 3CL\textsuperscript{pro}, has been shown to be essential for replication and has hence been recognized as a potent drug target for SARS infection. Currently, there is no effective treatment for this epidemic, despite the intensive research that has been undertaken since 2003 (over 3500 publications). This perspective focuses on the status of various efficacious anti-SARS-CoV 3CL\textsuperscript{pro} chemotherapies discovered during the last 12 years (2003-2015) from all sources, including laboratory synthetic methods, natural products and virtual screening. We describe here mainly peptidomimetic and small molecule inhibitors of SARS-CoV 3CL\textsuperscript{pro}. Attempts have been made to provide a complete description of the structural features and binding modes of these inhibitors under many conditions.

Key words: Severe acute respiratory syndrome, coronavirus, 3CL protease, inhibitors, infectious diseases and chemotherapy
1. Introduction

Coronaviruses have been known for more than five decades, since the first prototype murine strain, JHM, was reported in 1947.\textsuperscript{1,2} Viruses such as porcine transmissible gastroenteritis virus (TGEV), avian infectious bronchitis virus (IBV) and bovine coronavirus (BCoV) severely infect animals. The murine coronavirus mouse hepatitis virus (MHV) was studied as a model for the human disease. Although studies of the mechanism of replication as well as the pathogenesis of several coronaviruses have been very active since 1970s, this family of coronaviruses received much attention when it was recognized that a new human coronavirus was responsible for severe acute respiratory syndrome (SARS), a contagious and fatal illness.\textsuperscript{3,4}

![Taxonomy Diagram]

\textbf{Figure 1.} Schematic representation of the taxonomy of \textit{Coronaviridae} (according to the International Committee on Taxonomy of Viruses). SARS-CoV belongs to the \textit{Betacoronavirus} family but has a “b” lineage. *\textit{Coronaviridae} along with \textit{Arteriviridae}, \textit{Mesoniviridae}, and \textit{Roniviridae} are members of this family.
Coronaviruses belong to one of two subfamilies of (Coronavirinae and Torovirinae) of the family Coronaviridae, which in turn comprise the order Nidovirales (Figure 1). They are classified into four genera (α, β, γ, and δ), and each genus can be further divided into lineage subgroups. SARS-CoV belongs to the Betacoronavirus group (see Figure 1).

In 2003, a new human coronavirus was identified as an etiological agent of the first global pandemic of the 21st century, severe-acute respiratory syndrome (SARS), and the virus was named SARS-CoV. The first case of “an atypical pneumonia” was reported in China, during November 2002. Its rapid and unexpected spread to another 29 countries, mostly in Asia and North America, alarmed both the public and World Health Organization (WHO). Within a few months of this outbreak in 2003, the WHO announced in a cumulative report about its emergence that it had caused 916 deaths among 8422 cases (fatality rate of 10-15%) worldwide, as shown in Table 1. This incidence indicates how rapidly a contagious illness can spread in this highly interconnected society.

SARS is mainly characterized by a high fever (>38 °C), dyspnea, lymphopenia, headache and lower respiratory tract infections; concurrent gastrointestinal symptoms and diarrhea are also common. With the enormous efforts of the WHO and expert scientists from various countries, a novel human coronavirus was identified as the etiological agent for SARS. The sequence information of the coronavirus polymerase gene, along with all other previously characterized strains, demonstrated that this was a previously unrecognized coronavirus in humans. Although, the SARS epidemic was successfully controlled in 2003, the identification of animal reservoirs for this virus and the recent report of a new virus related to SARS, called Middle East respiratory syndrome (MERS), provide strong motivation for the development of anti-SARS agents to treat this potentially fatal respiratory illness.

The recent outbreak of MERS in South Korea alarmed the public, and the number of patients under quarantine was reported to be 1,600. After the first patient was diagnosed with MERS on May 20, 2015, within a period of 2 months, the total number of cases identified had increased to 186 with 36 fatalities and possible infection of 16,700 individuals who were subjected to isolation. By the end of August 2015, a total of 1511 patients were infected with this virus, of which 574 (~39%) had died after the first case was recorded in June 2012 in Saudi Arabia.
To date, the FDA has not approved an antiviral agent for the treatment of SARS, although the clinical treatments are directed toward symptomatic relief. Therefore, the development of effective antiviral chemotherapy against SARS-CoV is important for future outbreaks. Numerous reports (over 3500 publications) have been published on SARS-CoV since 2002. Recently, a brief review on the progress of anti-SARS chemotherapy was reported.\textsuperscript{25} However; no reports have been published about the substrate selectivity, mechanism of action, and SARs of the inhibitors. Therefore, to overcome the drawbacks and to enhance the qualitative understanding of the etiology, pathology, and possible therapeutic targets against this virus, a comprehensive review is currently needed.

\textbf{Figure 2.} Structure of a coronavirus showing proteins used for replication.

This perspective focuses on the status of SARS-CoV 3chymotrypsin-like protease (3CL\textsuperscript{pro}) inhibitors discovered during last 12 years from all sources, including laboratory synthetic methods, natural products, virtual screening and structure-based molecular docking studies. Attempts have been made to provide a complete description of the structural features (SARs) and detailed mechanisms of action of inhibitors. We believe that this perspective will comprise a cumulative source of SARS-CoV 3CL\textsuperscript{pro} inhibitors for researchers and further the understanding of anti-SARS chemotherapy.
2. SARS-CoV and structure of 3CL\textsuperscript{pro}

Coronaviruses are a family of positive strand, enveloped RNA viruses that can cause acute and chronic respiratory, enteric and central nervous system diseases in many species of animals, including humans.\textsuperscript{26,27} This family features the largest viral genomes (27-31 kb) found to date.\textsuperscript{28,29} The genomic RNA is complexed with the basic nucleocapsid (N) protein to form a helical capsid within the membrane. The membrane of all coronaviruses is comprised of a minimum of three viral proteins: (i) a spike protein (S), a type of glycoprotein I, (ii) a membrane protein (M) that spans the membrane and (iii) an envelope protein (E), a highly hydrophobic protein that covers the entire structure of the coronavirus (Figure 2).\textsuperscript{30} The SARS-CoV genome contains two open reading frames, connected by a ribosomal frame shift, which encode two large overlapping replicase polyproteins, pp1a (\textsim 450 kDa) and pp1ab (\textsim 750 kDa), from which the functional proteins are produced by an extensive proteolytic process.\textsuperscript{31,32} While other coronaviruses utilize three proteases for proteolytic processing, the SARS-CoV is known to encode only two proteases, which include a papain-like cysteine protease (PL\textsuperscript{pro})\textsuperscript{33} and a chymotrypsin-like cysteine protease known as 3C-like protease (3CL\textsuperscript{pro}).\textsuperscript{34-39} The 3CL\textsuperscript{pro} enzyme, also called Main protease (M\textsuperscript{pro}), is indispensable to the viral replication and infection process, thereby making it an ideal target for antiviral therapy.

The X-ray crystallographic structure of hexapeptidyl chlormethyl ketone (CMK) inhibitor bound to 3CL\textsuperscript{pro} at different pH values was solved by Yang et al in 2003 (see Figure 3).\textsuperscript{38} It was explained that SARS-CoV 3CL\textsuperscript{pro} forms as a dimer with the two promoters (denoted as “A” and “B”) oriented almost at right angles to each other (Figure 3A and B). The crystal structure of the SARS-CoV 3CL\textsuperscript{pro}, similar those of other 3CL\textsuperscript{pro}, comprises three domains. Domains I (residues 8-101) and II (residues 102-184) contain β-barrels that form the chymotrypsin structure, whereas domain III (residues 201-306) consists mainly of α-helices (Figure 3).\textsuperscript{38-40} SARS-CoV 3CL\textsuperscript{pro} has
a Cys-His catalytic dyad and the substrate or inhibitor binding site is located in a cleft between
domain I and II. The substrate-binding subsite S1 specificity in protomer A of a CoV protease
confers absolute specificity for the P1-Gln substrate residue on the enzyme. Each N-terminus
residue (N-finger) squeezed between domains II, III of the parent monomer and domain II of the
other monomer, plays an important role in dimerization and formation of the active site of 3CL\textsuperscript{pro}.
The SARS-CoV 3CL\textsuperscript{pro} dimer is highly active, while the monomer is principally inactive.\textsuperscript{41}

![Figure 3](image)

**Figure 3.** The SARS-CoV 3CL\textsuperscript{pro} dimer structure complexed with a substrate-analogue
hexapeptidyl CMK inhibitor (PDB ID: 1UK4).\textsuperscript{38} (A) The SARS-CoV 3CL\textsuperscript{pro} dimer structure is
presented as ribbons, and inhibitor molecules are shown as ball-and-stick models. Protomer A
(the catalytically competent enzyme) is shown in red, protomer B (the inactive enzyme) is shown
in blue, and the inhibitor molecules are shown in yellow. The N-finger residues of protomer B are
shown in green. The molecular surface of the dimer is superimposed. (B) A cartoon diagram
illustrating the important role of the N-finger in both the dimerization and maintenance of the
active form of the enzyme is shown. This figure 3 was adapted from Yang, H. \textit{et al} (permission
was granted for use of Figure 3 by PNAS publication “Copyright (2003) National Academy of
Sciences, U.S.A.”).\textsuperscript{38}

3. SARS-CoV 3CL<sup>pr</sup> inhibitors

In 2004, Kua <i>et al</i> reported the first preparation of the fully active dimeric SARS-CoV 3CL<sup>pr</sup> with the authentic sequence.<sup>42</sup> In order to screen for inhibitors of SARS-CoV 3CL<sup>pr</sup>, they prepared a peptide substrate with a fluorescence quenching pair 4-(4-dimethylaminophenylazo)benzoic acid (Dabcyl) and 5-[(2-aminoethyl)amino]naphthalene-1-sulfonic acid (Edans) at the N- and C-termini, respectively, which resulted extremely sensitive assay, and allowed many potent inhibitors of SARS-CoV 3CL<sup>pr</sup> to be identified.

3CL<sup>pr</sup> are cysteine proteases, which are analogues to the main picornavirus 3C protease, a family of viruses that also cause respiratory illness. The conservation of specificities within the 3CL<sup>pr</sup> family of coronaviruses has been reported with the amino acid sequence Leu-Gln-Ser or Leu-Gly-Ala as the preferred P2-P1-P1' sequence (Table 2).<sup>1</sup> Although the functional similarities of 3CL<sup>pr</sup> have “cleavage site-specificity” to that of picornavirus 3C proteases, the structural similarities between the two families are limited.<sup>43</sup> The SARS-CoV 3CL<sup>pr</sup> cleaves polyproteins at no less than 11 conserved sites involving the Leu-Gln↓(Ser, Ala, Gly) sequence, which appears to be a conserved pattern of the 3CL<sup>pr</sup> of SARS-CoV.<sup>3,37</sup> The active site of SARS–CoV 3CL<sup>pr</sup> contains Cys145 and His41 creating a catalytic dyad in which the cysteine functions as a common nucleophile in the proteolytic process (Figure 4).<sup>39,43,44</sup>
Figure 4. Natural amide substrate hydrolysis by Cys145 and His41 at the active site of 3CL<sub>pro</sub>.

The initial step in the process is deprotonation of Cys-thiol (I) and followed by nucleophilic attack of resulting anionic sulfur on the substrate carbonyl carbon (II). In this step, a peptide product is released that has an amine terminus, while histidine is restored its deprotonated form (III). In the next step, the resulting thioester is hydrolyzed (IV) to release a carboxylic acid, and the free enzyme (V) is regenerated in the final step. Therefore, the functional significance of 3CL<sub>pro</sub> in the viral life cycle makes this protease an ideal target for the development of drugs against SARS and other coronavirus infections.
In 2003, the first X-ray structure of the SARS-3CL\textsuperscript{pro} dimer with a peptidic CMK (1; Cbz-Val-Asn-Thr-Leu-Gln-CMK, see Figure 5) inhibitor was elucidated (Yang, H. \textit{et al}.).\textsuperscript{38} The unexpected binding mode of the substrate–analogue 1 provides a structural explanation for the P1-Gln entering into the specific pocket and for the decreased P2-Leu specificity of the SARS enzyme. However, specificities for P2-Leu and P4-Ser have been observed in the structure of 1 bound to TGEV 3CL\textsuperscript{pro},\textsuperscript{43} whereas P3-Thr is orientated toward bulk solvents. In addition, compound 2 or rupintrivir (\textit{AG7088})\textsuperscript{43} shown in Figure 5 has already been clinically tested for common cold (targeting rhinovirus 3C protease) binds to human rhinovirus 3C protease in the same orientation as that observed for the CMK inhibitor of TGEV. The X-ray crystal structure of 1 with TGEV 3CL\textsuperscript{pro} and superimposed 2 (\textit{AG7088}) with HRV2 3C\textsuperscript{pro} is depicted in Figure 6.

\textbf{Figure 5.} Chemical structures of inhibitors 1, 2 and 3.
Figure 6. (A) The crystal structure of 1 with TGEV 3CL\textsuperscript{pro} (PDB ID: 1P9U) and superimposed 2 with HRV2 3C\textsuperscript{pro} (PDB ID: 1CQQ). The protein binding pocket is shown in surface representation (pink color). The carbon color of compounds 1 (B), 2 (C), the binding pocket residues of TGEV 3CL\textsuperscript{pro} and HRV2 3C\textsuperscript{pro} are represented in magenta, green, dark and light grey, respectively. Oxygen atoms are colored in red, nitrogen atoms in blue, sulfur atoms in yellow and hydrogen atoms in white.

Since the substrate specificity of picornavirus 3C\textsuperscript{pro} for the P1-P1' and P4 sites is very similar to that of coronavirus 3CL\textsuperscript{pro}, compounds 1 and 2 have been proposed as a starting point in the development of new SARS-CoV 3CL\textsuperscript{pro} inhibitors (Figure 5).\textsuperscript{45-48} In addition, the HIV-1 protease inhibitor 3 (Figure 5)\textsuperscript{46,49} was found to have high binding affinity towards SARS-CoV 3CL\textsuperscript{pro} as well. Using the above three molecules as peptidomimetics, many medicinal chemistry studies have been focused on developing a potent chemotherapy method for SARS.

Drugs designed to treat SARS-CoV 3CL\textsuperscript{pro} can be broadly classified into two types: (i) peptidic inhibitors, which mimic natural peptide substrates and (ii) small molecule-based inhibitors,
obtained from modifications of existing protease inhibitors, virtual screening, structure-based molecular docking studies and natural products. Additionally, metal-conjugated inhibitors as well as some miscellaneous SARS-CoV 3CL\textsuperscript{pro} inhibitors are also discussed in this perspective.

4. Peptidomimetic inhibitors

In principle, a good substrate can be converted to a good inhibitor by replacement of a part of the substrate sequence that binds directly to the active site of the protease (reversible or irreversible) with the chemical “warhead” targeting the catalytic mechanism. Peptidic inhibitors were designed by attaching a chemical “warhead” type agent to a peptide that mimics the natural substrate. These warhead groups include Michael acceptors, aldehydes, epoxy ketones, halomethyl ketones and several others (For example see Figure 7). Mechanistically, these inhibitors act through a two-step procedure, wherein they first bind and form a non-covalent complex with the enzyme such that the warhead is located in close proximity to the catalytic residue. This is followed by a nucleophilic attack by the catalytic cysteine and covalent bond formation. In this perspective, the discussion of peptidomimetics is focused on the substrate selectivity to each specific site (S1'-S1-S2-S3-S4) of 3CL\textsuperscript{pro}, mode of action and SAR studies.

4.1. Peptides with a Michael acceptor

Peptidyl or peptidomimetic derivatives contain Michael acceptors as warheads and are an important class of cysteine protease inhibitors. In general, inhibitor design strategies involve the replacement of a substrate’s scissile amide bond with an appropriate Michael acceptor group. The inactivation of a cysteine protease by a Michael acceptor group is depicted in Figure 7. The cysteine residue undergoes 1,4-addition to the inhibitor at the Michael acceptor warhead group and the subsequent protonation of the \(\alpha\)-carbanion results in the irreversible inhibition of the enzyme.
Figure 7. Proposed mechanism of cysteine protease inactivation by inhibitors containing Michael acceptor groups.

The SAR study of compound 2 indicated that the inhibitory activity was improved by replacing the following side chain residues: the P1-lactam with a phenyl group (4) and the P2-fluorobenzyl with a benzyl group (5), as shown in Figure 8.\(^{50}\) It was noted that compound 5 had two P1 and P2-phenylalanine groups and could fit in the S2 and S3 pockets of SARS-CoV 3CL\(^\text{pro}\), respectively. In addition, the isoxazole moiety of these analogues adopted a conformation different from that of inhibitor 2 and thus undergoes hydrogen bonding with Gln192 in the S4 pocket. However, the conjugated ester was not accessible (>4.5 Å) to Cys145 to allow a Michael addition for covalent bond (C-S bond) formation. Consequently, this process was achieved by a subsequent strategy using pseudo-C2 symmetric analogues (6-9, Figure 8),\(^{50}\) thus exhibiting good inhibitory activity against 3CL\(^\text{pro}\). In particular, a compound comprised of Phe-Phe dipeptide unsaturated ester and 4-(dimethylaminocinnamic acid) (8) exhibited potent inhibitory activity with an IC\(_{50}\) value of approximately 1.0 µM and a K\(_i\) value of 0.52 µM. The cell-based bioassay gave an EC\(_{50}\) = 0.18 µM. The presence of a 4-dimethylamino moiety on the phenyl ring of these cinnamic analogues was found to be an important structural functionality for activity enhancement.
Another series of compounds were reported based on the modification of compound 2 at the P2 side chain by converting the p-fluorobenzyl group to a smaller benzyl (10) or prenyl group (11). These inhibitors (10 & 11) possess P1/P1′-Michael acceptor groups, which can covalently link to the Cys145 (Figure 8). The resulting analogues are not only potential inhibitors of SARS-CoV 3CLpro (K_{inact} values), but are effective in SARS-CoV cell-based bioassays. No toxicity was observed up to 100 µM. In addition, it was observed that compound 12 which contains a hydroxyethylene isostere (12) in place of the ketoethylene of compound 10 was inactive due to the loss of an important hydrogen bond interaction between the backbone amide nitrogen of
Glu166 and the carbonyl oxygen of the inhibitor (Figure 8).\textsuperscript{51} Further replacement of the P4-isoxazole unit with a Boc-serine and a P2-benzyl, prenyl or isobutyl (13-15: Figure 7)\textsuperscript{52} increased the inhibitory activity against 3CL<sub>pro</sub> to several times of that of the lead inhibitor (2) (IC<sub>50</sub> = 800 µM), which confirmed both the P4-Boc-serine and P2-isopropyl groups as important structural requirements for greater potency.

Although the activity of the potent analogue 13 was improved to several times that of compound 2 against SARS-CoV 3CL<sub>pro</sub>, substrate specificity for each site in 3CL<sub>pro</sub> could not be identified because the inhibitory activity was absolutely dependent on the other residues in these peptides. Therefore, the backbone structure of compound 2 was modified in a systematic manner as reported by Yang, S. \textit{et al.}\textsuperscript{53} As a result, a five-member lactam ring was found to be more specific for the P1-site, and leucine was used at the P2-site, which showed much better enzyme activity (>15-fold) than the other residues (Table 3). The strong binding of the five-member ring was evidenced by multiple hydrogen-bonds in the X-ray crystal structure (PDB ID: 2GX4).\textsuperscript{53} For the P2-site, replacement of phenylalanine or 4-fluorophenylalanine with a leucine group increased the inhibitory activity of the enzyme by 4-fold. This result indicated that the rigid and planar phenyl ring is not favorable for binding to the S2 hydrophobic pocket (16 and 17). A lipophilic tert-butyl group at the P3 site further enhances the binding affinity more than 10-fold (17 and 18).

Furthermore, the benzyloxy group was found to be the best replacement moiety for P4-methylisoxazole, resulting in a more than 4-fold increment in enzyme inhibitory activity (2 and 16); this group was found to be the best group for this site. Based on the docking study, this benzyloxy group has also been observed in a unique conformation in the X-ray crystal structure (docking study of 18 with PDB ID: 2GX4, see SI, Figure S1).\textsuperscript{53}

4.2. Peptides with Keto-glutamine

A novel series of keto-glutamine analogues (19-26) with a phthalhydrazido group at the \(\alpha\)-position were reported as reversible inhibitors against SARS-CoV 3CL\textsuperscript{pro} (Figure 9).\textsuperscript{54} This
discovery originated due to their inhibitory activity against the human hepatitis A virus 3C protease.\textsuperscript{55,56} These compounds feature $\beta$ and $\beta'$ functionalities adjacent to the keto group as well as intramolecular hydrogen bonding to the carbonyl, which makes them more electrophilic and susceptible to hemithioacetal formation with Cys145 in the active site of the protease. Compound 25 was recognized as the most potent analogue with an inhibitory value (IC$_{50}$) of 0.65 µM. SAR studies indicated that both $\gamma$-lactam and phthalhydrazide moieties are very important for good inhibition. Specifically, the introduction of the $\gamma$-lactam into the inhibitor containing a phthalhydrazide moiety greatly enhanced the inhibitory activity against SARS-CoV 3CL$^{\text{pro}}$ (compare inhibitors 19-22 vs 23-26). This was further supported by molecular modeling studies of the active inhibitors (24-26) which show binding via an extended $\beta$-sheet interaction with residues 163-166 of the 3CL$^{\text{pro}}$ and formation of hydrogen bonds between the His163 and the P1 side chain.

\begin{figure}
\centering
\includegraphics[width=\textwidth]{keto-glutamine.png}
\caption{Keto-glutamine derivatives with phthalhydrazide (19-27) and thiophene group (28).}
\end{figure}
A recent report disclosed the X-ray crystal structure of SARS-CoV 3CL\textsuperscript{pro} complexed with one of the phthalhydrazide (19)-based peptide inhibitors (Figure 10, PDB ID: 2Z3C).\textsuperscript{57} The inhibitor forms an unusual thiiranium ring with the nucleophilic sulfur atom of Cys145, trapping the enzyme’s catalytic residues in configurations similar to the intermediate states proposed to exist during the hydrolysis of the native substrate.\textsuperscript{57} Additionally, the data suggest that this structure resembles the proposed tetrahedral intermediate during the deacylation step of normal peptide hydrolysis cleavage.\textsuperscript{57} Furthermore, to prove the importance of P1-lactam and phthalhydrazide units in inhibitor 23, a series of analogues modified from P1-lactam to P1-phenyalanine (27) or from phthalhydrazide to thiophene (28) were reported to have only weak activity against SARS-CoV 3CL\textsuperscript{pro}.\textsuperscript{54}

\textbf{Figure 10.} The crystal structure of phthalhydrazide-based inhibitor 19 bound to SARS-CoV 3CL\textsuperscript{pro} (PDB ID: 2Z3C). The protein binding pocket is shown in surface representation and colored in orange. The carbon atoms of the inhibitor 19 and the binding pocket residues are shown in stick model and colored in green and yellow, respectively. The thiiranium ring formed by amino acid Cys145 is colored in magenta.
4.3. Peptides with nitroanilide

A diverse series of peptide anilides (29-35) were reported based on niclosamide (Figure 11). Unlike typical nitroanilide-based peptides, which are readily hydrolyzed by serine and cysteine protease, these peptides were not efficiently cleaved by SARS-CoV 3CLpro. Niclosamide showed no inhibitory activity at a concentration of 50 µM. The most potent inhibitor (29) is an anilide derived from 2-chloro-4-nitro aniline, L-phenylalanine and 4-(dimethylamino)benzoic acid. This anilide is a competitive inhibitor of the SARS-CoV 3CLpro with a $K_i$ value of 0.03 µM.

Figure 11. Anilide-type peptidomimetics (29-35) and (2S,3S)-aza epoxide (36) and trans-aziridine (37) inhibitors.
and showed high selectivity towards SARS-CoV 3CL\textsuperscript{Pro} (IC\textsubscript{50} = 0.06 \mu M) rather than other proteases such as trypsin (IC\textsubscript{50} = 110 \mu M), chymotrypsin (IC\textsubscript{50} = 200 \mu M), and papain (IC\textsubscript{50} = 220 \mu M). Due to the chlorine atom at the \(\sigma\)-position, the 2-chloro-4-nitrophenyl ring and amido group cannot be in a coplanar conformation, thus making hydrolysis unfavorable.

Figure 12. The docked pose of 29 (green, stick model) is shown with the binding pocket residues (grey, line model) and interacting residues (orange, stick model) with SARS-CoV 3CL\textsuperscript{Pro} (PDB ID: 1UK4). The binding pocket of the protein is shown in surface representation and grey in color.

Modification of compound 29 in a series of analogues resulted in reduced potency (30-35).\textsuperscript{58} A docking study (Figure 12, PDB ID: 1UK4) showed that the 2-chloro-4-nitroanilide unit of compound 29 occupies the second preferred pocket. Thus, the nitro group was predicted to be hydrogen bonded with Ala46 and His41, providing a possible key interaction with the catalytic dyad. The (dimethylamino)phenyl group fit into the cleft formed by Gln189-Gln192 and Met165-Pro68.\textsuperscript{58} A docking study also suggested that anilide 29 has the lowest binding energy (-9.1
kcal/mol) compared to the other derivatives. This experiment supports the observations of the enzymatic assay, which revealed the important roles of 2-chloro-4-nitroaniline and 4-(dimethylamino)benzoic acid residues in effective inhibition.\textsuperscript{58}

**4.4. Aza-epoxide and aziridine peptides**

It has been reported that some novel classes of aza-peptide epoxides (APEs) act as inhibitors for clan CD cysteine peptidase.\textsuperscript{60,61} In the compound library screening, compound 36, (Figure 11) showed prominent activity with irreversible inhibition of SARS-CoV 3CL\textsuperscript{pro} ($K_{\text{inact}}/K_i = 1900 (\pm 400) \text{ M}^{-1}\text{s}^{-1}$).\textsuperscript{62} From the kinetic data and crystal structure of APEs reported by Lee T-W. \textit{et al}, the 3CL\textsuperscript{pro} reacts only with the $S,S$-diastereomer and not its $R,R$-diastereomer. In addition, the epoxide C3 atom of APE must be in the $S$-configuration.

A comprehensive screening of various peptides with electrophilic building block-attached groups (e.g., epoxides and aziridines) identified potential 3CL\textsuperscript{pro} inhibitors. The data revealed that the aziridine- and oxirane-2-carboxylates are important for the inhibition of 3CL\textsuperscript{pro}. A trans-configured compound containing Gly-Gly-aziridine peptide 37 (54\% inhibition at 100 $\mu$M) was selected as a modest active-site directed irreversible SARS-CoV 3CL\textsuperscript{pro} inhibitor (Figure 11).\textsuperscript{63} This study also revealed that epoxide or aziridine building blocks alone, which do not contain an amino acid moiety, are not active.

**4.5. Peptide Aldehydes**

A series of peptide aldehyde libraries were designed to target the SARS coronavirus, based on the irreversible inhibitor CMK, and were shown to possess very weak inhibitory activity against SARS protease ($IC_{50} > 500 \mu$M).\textsuperscript{64} The inhibitor CMK binds in a canonical mode to TGEV 3CL\textsuperscript{pro} and resulted in a binding mode with P2, P4, and P5 addressing the respective S pockets,
while P3 and P6 were exposed to the solvent (Figure 13A). However, in monomer A SARS-CoV 3CL\textsuperscript{pro}, the CMK inhibitor follows a different side-chain orientation (noncannonical binding mode): P2, P4 and P6-residues were not positioned to the respective pockets of the enzyme but, remain solvent exposed. Instead, P3-threonine associates with the S2 pocket, and the S4 pocket is occupied by P5-asparagine (Figure 13B).

**Figure 13.** (A) CMK-canonical binding mode with TGEV 3CL\textsuperscript{pro} (PDB code 1P9U)\textsuperscript{43} CMK-noncanonical binding mode with active monomer A of SARS CoV 3CL\textsuperscript{pro} (PDB code 1UK4)\textsuperscript{38}, and (C) the derived inhibitors 38 and 39.
Based on these structural findings, it was observed that the sequential variations at the P sites of this initial structure produced potent inhibitors, especially after modifications of the P2 and P5 sites, whereas mutations of the P1 and P3 sites yielded only moderately improved inhibitors. Peptides 38 (AcNSTSQ-H) and 39 (AcESTLQ-H) were found to be more potent with the best reversible inhibitors having IC$_{50}$ values in the low micromolar range (7.5 µM) (Figure 13C). Interestingly, these inhibitors are assumed to bind in a noncanonical mode similar to that of CMK with TGEV 3CL$^{\text{pro}}$ (Figure 13B). In addition, the SAR suggested that the substrate specificity of SARS-CoV 3CL$^{\text{pro}}$ requires glutamine in the P1 position and a large hydrophobic residue in the P2 position. Moreover, X-ray crystal structures of some pentapeptide aldehydes Ac-ESTLQ-H (40, PDB ID:3SNE), Ac-NSFSQ-H (41, PDB ID:3SNA), Ac-DSFDQ-H (42, PDB ID:3SNB), and Ac-NSTSQ-H (43, PDB ID:3SNC), complexed with SARS-CoV 3CL$^{\text{pro}}$ revealed that the S2 pocket of the enzyme can accommodate serine and even an aspartic acid side chain in the P2 position (see SI, Figure S2). However, the cleavage efficiency of serine in the P2-position was 160 times lower than the original substrate (P2-Leu), and with aspartic acid, cleavage was not observed at all. Furthermore, the same research group also determined the X-ray crystal structure of SARS-CoV 3CL$^{\text{pro}}$ in complex with Cm-FF-H (44, K$_i$ = 2.24 µM, see Figure 14A). From the complex structure (see SI, Figure S3, PDB ID: 3SN8), compound 44 had a P1-phenylalanine residue located in the hydrophilic S1 subsite resulted in hydrophobic interactions with Phe140, Leu141, Asn142, and the P3-cinnamoyl group of Cm-FF-H. This result suggests that the stringent specificity of SARS-CoV 3CL$^{\text{pro}}$ with respect to the P1 and P2 positions can be overcome by the highly electrophilic character of the aldehyde warhead.
A novel potent SARS-CoV 3CL\textsuperscript{pro} peptide-aldehyde inhibitor (45: $K_i = 53$ nM) was developed as an anti-viral agent against SARS-CoV and human coronavirus HCoV 229E replication, which reduced the viral titer by 4.7 log (at 5 µM) for SARS-CoV and 5.2 log (at 1.25 µM) for HCoV 229E (Figure 14A).\textsuperscript{53} This inhibitor has distinct functional groups at the P1 to P4 sites compared to those of reference compound 2. This inhibitor was designed to evaluate the issues of cell viability, stability, and drug-like properties based on compound 18. Accordingly, the leucine moiety was replaced with a bulky cyclohexylalanine to improve the cell activity, and the ester group was replaced with an aldehyde to avoid hydrolysis by esterase. As a result, compound 45 (TG-0205221)\textsuperscript{53} displayed a very stable profile in mouse, rat and human plasma (Table 4).
X-ray crystal structure of 45 (PDB ID: 2GX4) revealed a unique binding mode comprising a
cova lent bond, hydrogen bonds and numerous hydrophobic interactions (see SI, Figure S4). 53

In the course of studies on the SARS-CoV 3CL pro and its inhibitors, 66 it was found that the mature SARS-CoV 3CL pro is very sensitive to degradation at the Arg188/Gln189 site, which causes a loss of catalytic activity. The stability of the SARS-CoV 3CL pro is dramatically increased by mutating the Arg at position 188 to Ile. The enzymatic efficiency of the R188I mutant was increased by a factor of more than 1×10^6. The potency of the mutant protease makes it possible to quantitatively evaluate substrate-based peptide-aldehyde inhibitors using conventional high-performance liquid chromatography (HPLC). A P-site pentapeptide sequence, Ac-Ser-Ala-Val-Leu-NHCH-(CH_2CH_2CON(CH_3)_2)-CHO (46: Figure 14B), inhibits the catalytic activity of the SARS-CoV 3CL pro with an IC_{50} value of 37 µM. The side-chain structures, especially at sites P1, P2, and P4, were then optimized step by step based on X-ray crystallographic analyses of the inhibitor-protease complex to provide potent tetra peptide aldehyde inhibitors (47 and 48) (Figure 14B). 67
4.6. Peptides with halomethyl ketone or electrophilic substituents

A new series of $N,N'$-dimethyl glutaminyl (49-53) or aspartic acid (54) inhibitors with fluoromethyl a ketone warhead were reported as SARS-CoV 3CL\textsuperscript{pro} inhibitors (Table 5).\textsuperscript{68} These inhibitors were designed based on their caspase inhibitory activities.\textsuperscript{69,70} Antiviral activity assessed by cytopathic effect (CPE) inhibition in SARS-CoV infected Vero cultures revealed that compounds effectively inhibit both FFM1 and 6109 strains of SARS-CoV replication.

Among these inhibitors, compound 49 exhibited promising activity with low toxicity in cells, protecting the cells with an EC₅₀ value of 2.5 µM and exhibiting a selectivity index >40. In addition, compound 49 showed low toxicity in mice. From the SAR studies, P1-glutamine, a residue that has been identified as a conservative recognition site in SARS-CoV 3CLₚ, can be replaced by N,N'-dimethyl glutamine (see 49-51). However, compound 54, a potent caspase inhibitor with P1-aspartic acid abolished activity in this series. Furthermore, the P2-leucine can also be replaced by isoleucine (50) and valine (51). The active compounds 49-51 were found to be inactive against rhinovirus type-2 in a cell based assay suggested that compounds 49-51 are specific against SARS-CoV. Compound 51 was found to have low toxicity in mice, after administration of a single dose at 25, 50, and 100 mg/kg. No weight loss or behavioral changes nor any gross pathology of the major organs was observed at the tested doses. This study suggested that compound 51 could be a promising candidate for animal efficacy studies. Abeles et al. proposed that trifluoromethyl ketones (FMK) can also be used as protease inhibitors. An interesting feature of these inhibitors is the formation of thermodynamically stable hemi-ketal or hemithioketal that occurs upon nucleophilic attack by the Ser-hydroxyl or Cys-thiol groups present in the serine or cysteine protease, respectively. Based on this observation, Hayashi et al. reported Gln-derived CF₃- ketones 55 and 56 as SARS-CoV 3CLₚ inhibitors (Figure 15). Compounds 55 and 56 showed modest inhibitory activity due to the formation of typical cyclic structures that are not expected to interact effectively with the active site. To avoid this problem, the sidechain at the P1 site was modified in order to block...
As shown in Figure 15, compounds 57 and 58 showed excellent activities and further optimization provided compounds 59-60, which showed low nanomolar inhibition of SARS-CoV 3CL\textsuperscript{pro}.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{inhibitors.png}
\caption{Inhibitors with halomethyl ketones and their derivatives 55-60.}
\end{figure}

While continuing to explore the SARs based on FMK inhibitors, a series of trifluoro methyl ketones 61-68 were developed mainly focusing on the P1 and P2-P4 positions (Table 6). Three
different amino acids were demonstrated as variable residues at positions P1-P4. The inhibitory activities were observed to range from 10-50 µM. The potent inhibitor, compound 61, which possesses the same moiety as the substrate sequence of the peptide at the P1-P4 sites, exhibited comparable activity to other compounds. As shown in Table 6, replacement of the P1-benzyl (62) with a methyl group (64) or hydrogen (66) resulted in a loss of activity. Inhibitor 61 showed time-dependent inhibition, with a $K_i$ value of 0.3 µM after a 4 h incubation.

4.7. Symmetric peptides

It was previously proposed that HIV protease inhibitors could serve as good starting points for the development of SARS-CoV 3CL\textsuperscript{pro} inhibitors. In general, reversible inhibitors produce fewer side effects than suicide inhibitors and are thus more suitable for drug development. Recently, compound 69, a non-covalent HIV protease inhibitor ($K_i = 1.5 \text{ nM}$), was used as a lead structure and optimized using computational analysis for the development of SARS-CoV 3CL\textsuperscript{pro} inhibitors.\textsuperscript{79} As shown in the Figure 16, introduction of peripheral Val-Ala residues in place of the Cbz groups, or introduction of 3-indolyl groups in place of the phenyl groups in compound 69 led to the formation of inhibitors (70 and 71) that were potent SARS-CoV 3CL\textsuperscript{pro} inhibitors with $K_i$ values of 0.34 and 0.073 $\mu$M, respectively. In addition, compound 71 is highly selective for the 3CL\textsuperscript{pro}, with no inhibition observed against HIV protease at 100 $\mu$M.

![Figure 16. Symmetric peptide diols 69-71.](image-url)
5. Small molecule inhibitors of SARS-CoV 3CL\textsuperscript{pro}

The other category of inhibitors against SARS-CoV 3CL\textsuperscript{pro} includes non-peptidic small molecules. In general, small molecules have been found to be non-covalent or reversible covalent inhibitors, which have advantages regarding side effects and toxicity, which often arise with covalent inhibitors. These inhibitors were discovered by high throughput screening, of synthetic compounds and natural products.

5.1. Etacrynic acid derivatives

An HPLC-based screen of electrophilic compounds revealed etacrynic acid derivatives 73, (75\% inhibition at 100 \mu M and \(K_I = 45.8 \mu M\)) and 74 (88\% inhibition at 100 \mu M and \(K_I = 35.3 \mu M\)) as effective inhibitors of SARS-CoV 3CL\textsuperscript{pro} \cite{80}. These inhibitors were obtained from the sequential modifications of an etacrynic acid (72), a well-known diuretic drug \cite{81} and also showed activity towards the cysteine proteases, such as papain protease (\(K_I = 375 \mu M\)) \cite{82}. Ester 73 showed more...
potency towards papain protease ($K_i = 3.2 \mu M$) than SARS-CoV 3CL\textsuperscript{pro} ($K_i = 45.8 \mu M$). However, etacrynic acid amide (74, $K_i = 35.3 \mu M$) was found to have more affinity toward SARS-CoV 3CL\textsuperscript{pro}. The SAR studies revealed that chloro substituents on the phenyl moiety were necessary for SARS-CoV 3CL\textsuperscript{pro} inhibition (Figure 17). Compounds with an unsubstituted phenyl ring or methyl substituent were inactive at 100 $\mu M$.\textsuperscript{80} In addition, it is quite promising that only esters or amides display 3CL\textsuperscript{pro} inhibition.\textsuperscript{80}

5.2. Isatin (2,3-dioxindole) inhibitors

It has been established that certain isatin (2,3-dioxindole) compounds are potent inhibitors of rhinovirus 3C\textsuperscript{pro}.\textsuperscript{83} Because the proteases of SARS-CoV and rhinovirus share similar active sites and catalytic residues,\textsuperscript{15} isatin derivatives may also be good candidates for anti-SARS drug development. Accordingly, a series of synthetic isatin derivatives (75-81) were reported as non-covalent SARS protease inhibitors,\textsuperscript{84,85} unlike rhinovirus 3C\textsuperscript{pro}, which has a covalent bond binding mode (Table 7). These isatin derivatives inhibited SARS-CoV 3CL\textsuperscript{pro} in the low micromolar range and inhibitors 78 and 80 were found to be the most potent. SAR studies revealed that the inhibitory potency heavily depended on the hydrophobicity and electron affinity of the substituents on the isatin core. Moreover, computational analysis (docking studies of 78 with PDB ID: 1UK4, see SI, Figure S5) of both active compounds showed that they fit very well into the active pocket of SARS-CoV 3CL\textsuperscript{pro}. The two carbonyl groups on isatin could form hydrogen bond interactions with the NH groups on Gly-143, Ser-144, Cys145 and the His-41 side chain. In addition, compounds 78 and 80\textsuperscript{86} exhibited better selectivity for SARS than for other proteases including papain (103, 87.24 $\mu M$), chymotrypsin (1 mM, 10.4 $\mu M$) and trypsin (362, 243 $\mu M$).

5.3. Flavonoid and biflavonoid derivatives

Chemothorapeutic agents that target viral entry are an important class of antiviral therapy as they can block the propagation of the virus at an early stage, thus minimizing the chance for the virus to evolve and acquire drug resistance. Screening of Chinese herbal medicine-based molecules resulted in the discovery of luteolin (82) as inhibitor of wild-type SARS-CoV activity with an
effective concentration (EC$_{50}$) of 10.6 µM (Figure 18). Compound 82 was identified as active using a two-step screening method consisting of frontal affinity chromatography-mass spectrometry coupled with a viral infection assay based on a human immunodeficiency virus (HIV)-luc/SARS pseudotyped virus. This flavone analog binds with the surface spike protein of SARS-CoV and thus can interfere with the entry of the virus into the host cells. However, the related flavone quercetin (83) and its derivatives exhibited modest inhibitory activity against the SARS virus (Figure 18).

Quercetin-3-β-galactoside (84) was identified as a potential inhibitor of SARS-CoV and showed inhibitory activity with an IC$_{50}$ of 42.79 ± 4.97 µM in a SPR/FRET-based enzymatic inhibition assay. The docking study of 84 with SARS-CoV 3CL$_{pro}$ suggested that the residue Gln189 (Q189) plays a key role in the binding interaction. In order to confirm this prediction, the binding mode of 84 was compared between the wildtype SARS-CoV 3CL$_{pro}$ and its mutated SARS-CoV 3CL$_{pro}$ Q189A. This comparative study was consistent with the docking prediction and the inhibitory potency of 84 on SARS-CoV 3CL$_{pro}$ Q189A was significantly decreased to 127.89 ± 10.06 µM. Besides, the experimental evidence showed that the enzymatic activity of SARS-CoV 3CL$_{pro}$ was not affected by the Q189A mutation. The L-fucose derivative (85) exhibited two-fold potent inhibitory activity compared to 84. The SAR and molecular docking studies of these new derivatives revealed that four hydroxy groups on the quercetin moiety are key determinants for its potential biological activity.

As part of ongoing investigation of bioflavonoids from medicinal plants as potential SARS-CoV 3CL$_{pro}$ inhibitors, a series of inhibitors (86-90) were reported from the leaves of Torreya nucifera (Figure 18). Among the isolated compounds, biflavone amentoflavone (86) was recognized as a potent non-competitive inhibitor, exhibiting an IC$_{50}$ value of 8.3 µM. An SAR study demonstrated the three authentic flavones, apigenin (90), luteolin (82) and quercetin (83), showed
inhibitory activities (IC$_{50}$) of 280.8, 20.2 and 23.8 µM, respectively. The activity of amentoflavone (86) was consistent with the binding interactions (docking studies of 86 with PDB ID: 2Z3E, see SI, Figure S6 with) with Val186 and Gln192 as one of the key binding modes with the target site. Moreover, the binding energy difference between apigenin (90; -7.79 kcal/mol) and amentoflavone (86; -11.42 kcal/mol) are consistent with a 30-fold lower IC$_{50}$ value of 86 toward SARS-CoV 3CL$^{pro}$ than apigenin (90).

*Figure 18. Flavonoids and biflavonoid derivatives.*
5.4. Terpenoid derivatives

A series of diterpenoids (91-93) from *Torreya nucifera* were evaluated for their anti-SARS activity (Figure 19). However, these terpenoids exhibited very low activity compared to biflavonoids against SARS-CoV 3CL\textsuperscript{pro} at concentrations up to 100 µM. One exception was ferruginol (91, IC\textsubscript{50} = 49.6 µM), which exhibited significantly greater activity. Moreover, the quinone-methide triterpenoids celastrol (94), pritimererin (95), tingenone (96) and iguesterin (97) were isolated from the methanol (95%) extracts of *Tripterygium regelii* (Celastraceae) and showed moderate inhibitory activities with IC\textsubscript{50} values of 2.6, 9.9, 5.5 and 10.3 µM, respectively, whereas the corresponding a semi-synthetic analogue dihydrocelastrol (98: IC\textsubscript{50} = 21.7 µM) reduced the inhibitory potency (Figure 19). A SAR study suggested that the quinone-methide moiety in the A ring and the more hydrophobic E-ring assist in producing the potent inhibitory activity. The compounds mentioned above (91-98) have been proven to be competitive inhibitors using kinetic analysis.

Furthermore, abietane-type diterpenoids and lignoids exhibit a strong anti-SARS-CoV effect. In particular, betulinic acid 99 and savinin 100 were shown to act as competitive inhibitors against SARS-CoV 3CL\textsuperscript{pro} with the K\textsubscript{i} values of 8.2 µM and 9.1 µM, respectively (Figure 19). On the basis of molecular modeling analysis, it was observed that the competitive inhibition of 99 and 100 on SARS-CoV 3CL\textsuperscript{pro} activity was consistent with the formation of multiple hydrogen bond interactions between the compound and specific amino acid residues located at the active site of the pocket of the protease enzyme.
5.5. Sulfone, dihydroimidazole and \(N\)-phenyl-2-(2-pyrimidinylthio)acetamide type analogues

Structure-based virtual screening of a chemical database containing 58,855 compounds for SARS-CoV 3CL\(^{\text{pro}}\) inhibition produced two hits, sulfone (101) and dihydroimidazole (102)
The core structures of these two hits, defined by a molecular docking study, were used for further searches of analogues.

Accordingly, twenty-one analogues derived from these two hits exhibited IC$_{50}$ values below 50 µM, and the two most potent compounds (103 and 104) obtained from each hit show IC$_{50}$ values...
of 0.3 and 3 μM, respectively. Furthermore, a combination of structure-based virtual screening and three-dimensional quantitative structure-activity relationship (3D-QSAR) studies of compound databases of 59,363 compounds led to the identification of compounds 105-110, which exhibited modest inhibition with IC$_{50}$ values of 3, 10, 11, 12, 14 and 15 μM, respectively (Figure 20). Based on the structure-functional analysis, a common core structure, N-phenyl-2-(2-pyrimidinylthio)acetamide, was identified. A potential binding mode of compound 105 was predicted by the molecular modeling study (docking study of 107 with PDB ID: 1UK4, see SI, Figure S7); the strong interaction of benzene and thiazole units with Glu166, Leu167, Pro168, and Gln192 at the SARS-CoV 3CL$_{pro}$ active site could explain its increase in potency.

5.6. Active heterocyclic ester analogues

Wong and co-workers$^{94}$ reported a novel class of mechanism-based irreversible inhibitors with activity in the nanomolar range, using combinatorial synthesis in microtiter plates followed by in situ screening.$^{95-97}$ Instead of the expected amide reaction products, a series of benzotriazole esters (111-114) were isolated. Surprisingly, the inhibitory activity of these analogues was much higher than that of the other small molecules or peptidomimetics. Further SAR optimization yielded analogues 115-118 with nanomolar inhibitory activities (Figure 21). An interesting point was found that the esters derived from the benzoic acid-containing electron withdrawing substituents e.g., NO$_2$, CN and CF$_3$ were susceptible to hydrolysis, whereas esters 111-114 and those with electron-donating substituents were relatively stable in pH 5.0-8.0 solutions over 24 h at room temperature. Compound 116 (K$_i$ = 7.5 nM) was the most potent among the benzotriazole esters.$^{94}$ The possible mode of action could be acylation of Cys145 at the active site assisted by the catalytic dyad; this irreversible enzyme acylation was verified by electrospray ionization mass spectrometry of the inhibited enzyme with the compound 112 (Figure 22).
Figure 21. Active heterocyclic ester analogues and their inhibitory activities against SARS-CoV 3CL\textsuperscript{pro}.

In addition, the recent X-ray crystal structure of the SARS-CoV 3CL\textsuperscript{pro} complex with the benzotriazole ester also confirmed that the active-site cysteine is acylated by the ester ligand.
which acts as a suicide inhibitor.\textsuperscript{98} It should be noted that the formation of \textit{N}-hydroxybenzotriazole is a very potent inhibitor of CYP450 enzymes. Heteroaromatic ester \textbf{119} (IC\textsubscript{50} = 0.5 µM) was also identified as a potent inhibitor of the SARS coronavirus.\textsuperscript{99} The 5-chloropyridine moiety in compound \textbf{119} proved to be the key unit for activity against SARS-CoV 3CL\textsuperscript{pro}. Continuing SAR studies provided the very potent inhibitors \textbf{120-123}, with inhibitory activities spanning from the micromolar to nanomolar range.

The structural biology analysis suggested, in addition to the halopyridyl unit, the other aromatic rings are also key factors for potent inhibition (Figure 21).\textsuperscript{100,101} A covalent bond formation mechanism for the enzyme-inhibitor complex (\textbf{120}) has been proposed on the basis of electrospray mass spectrometry investigation (Figure 22).

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure22.png}
\caption{Mechanism of covalent bond formation of inhibitors \textbf{112} and \textbf{120} with the active site cysteine residue of SARS-CoV 3CL\textsuperscript{pro}.}
\end{figure}

However, another strategy was demonstrated by combining key parts of the previously mentioned mechanism-based inhibitors (\textbf{116} and \textbf{119}) to produce a novel series of 5-chloropyridinyl indolecarboxylate inhibitors (\textbf{124-128}) with enzymatic potency in the submicromolar range.
The SAR study suggested that the positions of the carboxylic acid ester and free indole hydrogen (NH) are critical for activity. Indole carboxylate 124 with carboxylate functionality at position 4 was the most potent inhibitor with an enzyme inhibitory activity (IC$_{50}$) of 30 nM and an antiviral EC$_{50}$ value of 6.9 µM.

![Chemical Structures](image)

**Figure 23.** Active 5-chloropyridine ester analogues and their inhibitory activity against SARS 3CL$_{pro}$.

### 5.7. Aryl methylene ketones and fluoro methylene ketones

5-Halopyridinyl-3-aromatic esters, as described in a previous section 5.6, act as highly potent inhibitors of SARS-CoV 3CL$_{pro}$ with IC$_{50}$ values in the low nanomolar range. They initially bind competitively and strongly to the active site, but are then hydrolyzed by the enzyme as substrates and released. Despite their potent inhibition of SARS-CoV 3CL$_{pro}$ and relatively long half-life in buffer at neutral pH values, they are likely to be problematic as drug candidates due to their propensity to be rapidly hydrolyzed by lipase, esterase and other enzyme in the mammalian cells. Moreover, these compounds can also potentially react non-specifically with other thiols or...
nucleophiles in mammalian cells, thereby leading to toxicity. Therefore, to develop stable and non-covalent inhibitors based on pyridinyl esters, a group of methylene ketones and corresponding mono and di-fluorinated methylene ketones were reported as SARS-CoV 3CL\textsuperscript{pro} inhibitors by Zhang, J. et al. (Figure 24).\textsuperscript{103} Compounds 129, 131 and 132 showed the best inhibition, and specifically, inhibitor 129 was the most potent among these analogues. The molecular modeling study of these active ketone analogues predicts a binding conformation similar to that of corresponding pyridinyl esters.\textsuperscript{100,101} A SAR study suggested that fluorination decreases inhibition despite enhancing the electrophilicity of the carbonyl carbon. Enzymatic analysis and ESI-MS studies indicate that these inhibitors utilize a non-covalent, reversible mechanism of action.

![Methylene ketones](image1)

**Figure 24.** Halomethyl pyridyl ketones and their inhibition potential against SARS-CoV 3CL\textsuperscript{pro}.

5.8. Pyrazolone and Pyrimidines

High throughput screening identified 3,3-dihydropyrazolidine 133\textsuperscript{104} and tetrasubstituted pyrazole 134\textsuperscript{105}, which displayed 1,3,5-triaryl substitution patterns, as SARS-CoV 3CL\textsuperscript{pro}
inhibitors. Further exploration of SAR produced a series of pyrazolones that demonstrated inhibitory activities against SARS-CoV 3CL\(^{pro}\) (Figure 25).\(^{106}\) Among them, compounds 135-137 exhibited potent inhibitory activities with the IC\(_{50}\) values of 5.5, 6.8 and 8.4 µM, respectively.

![Pyrazolones and pyrimidines](image)

**Figure 25.** Pyrazolones and pyrimidines and their inhibition potential against SARS-CoV 3CL\(^{pro}\).

Structure-functionality analysis indicated that the 4-carboxylbenzylidine-aryl ring attached to C4-of pyrazolone accompanied by electron withdrawing groups, such as CN, NO\(_2\) and F, favors inhibitory activity. Molecular modeling studies of the active compound 137 predicted that the N1-phenyl group located in the S1 pocket and the carboxyl benzylidene group in the S3 pocket of
3CL<sub>pro</sub> is crucial for its inhibitory activity. Pyrimidine derivatives (138-140) were designed, and their anti-SARS activity was reported (Figure 25).<sup>107,108</sup> Compound 140 was the most potent inhibitor that showed enzyme inhibitory activity (IC<sub>50</sub> = 6.1 µM) against SARS-CoV 3CL<sub>pro</sub>. SAR studies revealed that the presence of nitro functionality at position 4 on the benzylidene ring was more important for activity enhancement. This potent activity was consistent with a molecular docking study (docking study of 140 with PDB ID: 1UK4, see SI, Figure S8);<sup>38</sup> the oxygen of the nitro group formed a hydrogen bond with side chains of Gly143 and Cys145. In addition, the 4-chloro phenyl ring was predicted to fit into the S2 pocket due to hydrophobic interactions.

### 5.9. Decahydroisoquinoline derivatives

Starting from the peptide inhibitor 47 (see section 4.5),<sup>67</sup> a novel non-peptide decahydroisoquinoline inhibitor was designed and synthesized based on the cleavage site interactions at the S1, and hydrophobic interaction at the S2 sites of SARS SARS-CoV 3CL<sub>pro</sub>.<sup>109</sup> The decahydroisoquinoline inhibitors (141-144, Figure 26) showed weak inhibitory activities for SARS-CoV 3CL<sub>pro</sub>, which confirmed that the fused ring structure of the decahydroisoquinoline scaffold can be accommodated in the active site of SARS-CoV 3CL<sub>pro</sub>. From the X-ray crystallographic studies (PDB ID: 4TWW), it was confirmed that the decahydroisoquinoline inhibitors were at the active site cleft of 3CL<sub>pro</sub>, as observed in peptide–aldehyde inhibitors. The decahydroisoquinoline scaffold was inserted into a large S2 pocket and occupied most of the pocket. The P1 site imidazole was inserted into the S1 pocket as expected. These interactions were effective in holding the terminal aldehyde tightly inside the active site cleft, which resulted in the compact fitting of the novel scaffold to SARS-CoV 3CL<sub>pro</sub>. 
Figure 26. Novel Decahydroisoquinoline derivatives as SARS-CoV 3CL\textsuperscript{pro} inhibitors.

5.10. 3-pyridyl and benzotriazole based SARS-CoV 3CL\textsuperscript{pro} inhibitors

Jacobs \textit{et al} conducted a high-throughput screening of NIH molecular libraries (~293,000 compounds) by evaluating the inhibition of 3CL\textsuperscript{pro} mediated peptide cleavage using a novel FRET-based substrate\textsuperscript{110,111}. In this screen a dipeptide class, represented by 3-pyridyl based hit 145 (Figure 27) was identified.

Optimization study based on derivatives (Ugi library) structurally related to hit compound 145 resulted in a series of 3-pyridyl based inhibitors among which the two compounds, 146 and 147 (Figure 27) were shown to be active against SARS-CoV 3CL\textsuperscript{pro}.
The X-ray crystal structure of 146 bound to SARS-CoV 3CL\textsuperscript{pro} (Figure 28) demonstrated that the binding orientation of 146 was similar to that of known covalent peptidomimetic inhibitors (for example compound 11), and preferentially occupies the S3-S1' subpockets of SARS-CoV 3CL\textsuperscript{pro} enzyme as R-enantiomer. The tert-butyl amide occupies the S3-pocket, the tert-butylanilido group occupies the deep S2-pocket, and the 3-pyridyl moiety occupies the S1; the furyl amide acts as a P1’ group. Inhibitor 146 lacks a reactive warhead.
**Figure 28**: The X-ray crystal structure of 146 bound to the binding pocket SARS-CoV 3CL\textsuperscript{pro} (PDB ID: 3V3M). The pockets S1' - S3 is highlighted and the compound 146 is represented in stick model and colored in cyan.

Based on the SAR for 146 and related analogs, first a chemical library focusing exclusively on the P1’ group was synthesized, while holding the P1-P3 groups constant. This resulted in a series of inhibitors.\textsuperscript{110} The SAR study around P1’ of 146 showed that the five membered \(\pi\)-excessive heterocycles proved the most successful 148-153 (Figure 29A). Especially, compound bearing imidazole (150) and 5-chlorofuran (152) analogue exhibited equipotent to 146 with an IC\textsubscript{50} value of 6.0 µM and 5.2 µM respectively. Next, the P1 3-pyridyl unit in 146 was replaced with its isosteres, in order to identify alternate hydrogen bond acceptor groups. This effort led to identify another set of compounds (154-156, Figure 29B). Among them only pyridazine (154) and pyrazine (155) were tolerated, although no improvement was found around the pyridyl ring over 146. Both 2-and 4-pyridyl (156) analogues were not tolerable and reduced the potency.\textsuperscript{110}
Figure 29: SAR studies at the P1’ (A) and P1 sites (B) of 146 and chiral separation of 146 (R&S) (C) to 146-(R) and 146-(S) enantiomers.

In a continuing study the racemic compound 146 was purified by chiral supercritical fluid chromatography to separate 146-(R) (ML188)\textsuperscript{110} and 146-(S) enantiomers (Figure 29C). The evaluation of a compound 146-(R) exhibited inhibitory activity with an IC\(_50\) of 1.5 ± 0.3 µM.
against SARS-CoV 3CL\textsuperscript{pro}, while other enantiomer 146-(S) was inactive. The mechanism of inhibition of SARS-CoV 3CL\textsuperscript{pro} by 146-(R) was determined to be competitive (K\textsubscript{i}, 1.6 ± 0.26 μM) with non-covalent inhibition. Owing to the excellent 3CL\textsuperscript{pro} inhibition and antiviral activity (12.9 ± 0.7 μM) against mock-infected and SARS-CoV infected Vero E6 Cells, 146-(R) was elected as a first in class probe candidate from the furyl amide.

Following the identification of probe compound 146-(R), the same research group continued their further efforts to develop potent, non-covalent SARS-CoV 3CL\textsuperscript{pro} inhibitors based upon a chemical class of benzotriazoles from MLPCN screening.\textsuperscript{112} This resulted in a hit compound 157 (Figure 30A) demonstrating a SARS-CoV 3CL\textsuperscript{pro} IC\textsubscript{50} of 6.2 μM and good selectivity versus PL\textsuperscript{pro} (IC\textsubscript{50}>60 μM).
Figure 30. (A) SAR studies at the P1, (B) P2-P1’ and (C) P3-truncation of hit 157 to inhibitors (158-167).
The X-ray crystal structure of 157 bound to SARS-CoV 3CL\textsuperscript{pro} shows the diamide 157 binds into an induced-fit binding site that is formed by a rearrangement of the Gln189 and Met49 residue side chains (PDB ID: 4MDS, Figure 31). This induced fit site accommodates the syn N-methyl pyrrole and anilido acetamide moieties of the inhibitors within subpockets that can be characterized as S2-S4 and S2-S1’ subpockets, respectively. Figure 30A schematically illustrates the inhibitor-active site interactions oriented in a similar manner as depicted in Figure 31.

**Figure 31.** The X-ray crystal structure of 157 bound to SARS-CoV 3CL\textsuperscript{pro} (PDB ID: 4MDS) is represented in surface model. The compound 157 (green) is shown in stick model, the interacting residues (magenta) and the binding pocket residues (grey) are shown in line model.

In order to improve the activity, first the SAR study focusing on benzotriazole replacements in 157 for alternate hydrogen bond acceptor functionality was demonstrated. This resulted the replacement of benzotriazole with 4-phenyl 1,2,3-trizole 158 (IC\textsubscript{50} of 11 µM, Figure 30A) was tolerable.
Second the acetamide modification (P2-P1’ region) with a series of cyclic and acyclic congeners yielded many inhibitors which show activities below 10 µM (159-162, Figure 30B). Specifically the branched i-propyl derivative (159) and cyclobutylamide (160) having the greatest activity below 5 µM.

Third the researchers turned to P3-truncation for minimum pharmacophore to reduce overall molecular weight. This effort led to a series of analogues and SAR proved that truncated amides (163-167, Figure 30C) have comparable activity versus the elaborated amides; for example, compare 163-167 Vs 159-162. The compound 167 represented the first sub-100 nM inhibitor for the series and one of the most potent non-warhead based SARS-CoV 3CLpro inhibitors to date.

From the above compounds, one of the potent inhibitors, 165 (ML300)\(^{112}\) was selected for probe declaration.\(^{113}\) The biological profiles of inhibitors 146-(R), 160 and 165 are indicated in Figure 32. Relative to probe 146-(R) and the equipotent diamide 160, the compound 165 proved to offer progresses in several areas. Inhibitor 165 is ~100 amu lower MW (MW = 431) relative to 160 with moderate ligand efficiency (LE).\(^{114}\) Moderate cLogP value of 165 (cLogP = 3.2) greatly improves ligand efficiency-dependent lipophilicity (LELP)\(^{114}\) versus 146-(R) and 160. When both probe 146-(R) and 165 tested in an in-house in vitro DMPK panel including plasma protein binding, P450 enzyme inhibition, and intrinsic clearance using liver microsomes, both 146-(R) and 165 possess good free fraction. However, intrinsic clearance indicates both 146-(R) and 165 are predicted to be highly cleared. 146-(R) and 165 possess modest P450 enzyme inhibition; with 165 maintaining 5–10 µM activity across four major CYP enzymes (see Figure 32). Probe 165 was found to be highly selective in a Eurofins lead-profiling screen\(^{115}\) with only modest activity (10 µM) for melatonin MT1 receptor in a radioligand binding assay.
In vitro DMPK and ancillary pharmacology:

6. Metal conjugated SARS-CoV 3CL\text{pro} inhibitors

Metal ions have been shown to inhibit many viral proteases such as 3CL\text{pro} of noroviruses, papain-like protease (PLP2) of SARS-CoV, human cytomegalovirus (hCMV) protease and hepatitis C virus (HCV) NS3 protease.\textsuperscript{116-120} The screening of 960 metal conjugated compounds allowed inhibitors with potent inhibitory activity against SARS-CoV 3CL\text{pro} to be identified. These include competitive inhibitors phenyl mercuric acetate (168, \(K_i = 0.7 \mu M\)), thimerosal (169, \(K_i = 2.4 \mu M\)), and phenyl mercuric nitrate (170, \(K_i = 0.3 \mu M\)) (Figure 33).\textsuperscript{121,122} However, inhibition was more pronounced using zinc-conjugated compounds (171-174), i.e., 1-hydroxypyridine-2-thione zinc (171, \(K_i = 0.17 \mu M\)) compared to Zn\textsuperscript{2+} ions alone (\(K_i = 1.1 \mu M\)).

The X-ray crystal structure of SARS-CoV 3CL\text{pro}-168 (PDB ID: 1Z1I) revealed that phenyl-bound mercury occupied the S3 pocket, which is responsible for its enzymatic activity. Hg(II)
ions are known to cause toxic effects because the affinity of Hg$^{2+}$ ions to thiol groups in proteins leads to non-specific inhibition of cellular enzymes.$^{123}$ However, regarding the structures of zinc-centered complexes, the zinc ion plays a key role in targeting the catalytic residues via binding to the His41-Cys145 catalytic dyad to yield a zinc central tetrahedral geometry. This type of inhibition was similar to the zinc-mediated serine protease inhibitor keto-BABIM-$\text{Zn}^{2+}$ for trypsin in that a zinc ion was coordinated to the two chelating nitrogen atoms of bis(5-amidino-2-benimidazilyl)methane (BABIM) and the two catalytic residues (His-Ser) of trypsin in the tetrahedral geometry.$^{124}$ The safety of zinc-containing compounds for human use has been indicated by the fact that zinc acetate and zinc sulfate are added as supplements to drugs for the treatment of Wilson’s disease and Behcet’s disease, respectively.$^{125,126}$ Moreover, the possibility of zinc complexes incorporated into cells through the cell membrane was also demonstrated by studies on type-2 diabetic treatment.$^{127}$

Analysis of the active site cavity of this SARS-cysteine protease reveals the presence of a subsite contains a cluster of serine residues (Ser139, Ser144, and Ser147) and is an attractive target for the design of high affinity small molecule inhibitors. This cluster is conserved in all known coronavirus proteases. In particular, Ser139 and Ser147 are conserved in all known coronavirus. Due to the known potential reactivity of boronic acid compounds with the hydroxyl group of the serine residue, a series of bifunctional boronic acid-conjugated compounds (175-177) have been reported against SARS-CoV 3CL$^{\text{pro}}$ enzyme (Figure 33).$^{128}$ The greatest improvement in affinity was achieved with an amide type compound (177) with a $K_i$ of 40 nM. Isothermal titration microcalorimetric experiments indicated that these inhibitors bind reversibly to SARS-CoV 3CL$^{\text{pro}}$ in an enthalpically favorable manner, implying that they establish strong interactions with the protease molecule.
7. Miscellaneous SARS-CoV 3CL\textsuperscript{pro} inhibitors

Over the past decade, \textit{in silico} virtual screening (VS), in particular structure based virtual screening (SBVS), has emerged as a reliable, cost-effective and time-saving technique for the discovery of lead compounds as an alternative to high throughput screening (HTPS).\textsuperscript{129} The application of VS to the discovery of new enzyme inhibitors involves docking, computational fitting of the compound structure to the active site of an enzyme, and scoring and ranking of each compound.\textsuperscript{130} Based on the structural information, 361,413 structurally diverse small molecules were screened by a “genome-to-drug-lead” approach. Compound 178 showed modest activity against targeted human SARS-CoV 3CL\textsuperscript{pro} Toronto-2-strain with an EC\textsubscript{50} of 23 µM (Figure 34).
Virtual screening of 50,240 structurally diverse small molecules allowed 104 compounds with anti-SARS-CoV activities to be identified.\textsuperscript{131} Inhibitor 179 showed potent inhibitory activity with an IC\textsubscript{50} value of 2.5 µM and an EC\textsubscript{50} of 7 µM in a Vero cell-based SARS-CoV plaque reduction assay (Figure 34). Another group of researchers, using a quenched fluorescence resonance energy transfer assay, screened 50,000 drug-like molecules, resulting in 572 hits.\textsuperscript{99} After applying a series of virtual and experimental filters, five structurally novel molecules were identified that showed potent inhibitory activity (IC\textsubscript{50} = 0.5 ~ 7 µM) against SARS-CoV 3CL\textsuperscript{pro}.

\textbf{Figure 34.} Miscellaneous SAR-CoV 3CL\textsuperscript{pro} inhibitors. Among them, compounds 180 (IC\textsubscript{50} = 4.3 µM) and 181 (IC\textsubscript{50} = 4.3 µM) (Figure 34) showed good inhibitory activity of SARS-CoV 3CL\textsuperscript{pro} and exhibited interesting selectivity with no inhibition against other proteases tested (HAV 3C\textsuperscript{pro}, NS3\textsuperscript{pro}, chymotrypsin and papain).\textsuperscript{99}
The elucidation of the crystal structure of SARS-CoV 3CL\textsuperscript{pro} provided enormous opportunities for the discovery of inhibitors through rational drug design. As part of an effort to discover small molecule inhibitors of SARS-CoV 3CL\textsuperscript{pro}, structure based virtual screening of 32,000 small molecules was screened against the SARS-CoV 3CL\textsuperscript{pro} enzyme.\textsuperscript{47} Use of knowledge-based filters yielded 27 molecules for follow-up. A biological evaluation of the inhibitors in the low micromolar range found two compounds, \textbf{182} and \textbf{183}, with IC\textsubscript{50} values of 18.2 and 17.2, respectively (Figure 34). It has been reported that several nucleoside derivatives have 6-chloropurine as a nucleobase showed potent antiviral activity against some types of viruses.\textsuperscript{132,133} Because 6-chloropurine analogues are known to inhibit bacterial RNA polymerases, a series of nucleoside analogues with 6-chloropurines were evaluated for anti-SARS-CoV activity by a plaque reduction activity.\textsuperscript{134} Among them, two compounds, \textbf{184} and \textbf{185}, exhibited modest anti-SARS-CoV activity (IC\textsubscript{50} values of 48.7 and 14.5 \textmu M, respectively) that was comparable to those of mizoribine and ribavirin (Figure 34). This study revealed several SAR trends such as a 6-chloropurine moiety, 5'-hydroxy and protected (benzylated)-5'-hydroxy group are responsible for the potent inhibitory activity.

Ribavirin, a broad-spectrum of inhibitor of RNA and DNA viruses, was used for the treatment of SARS affected patients,\textsuperscript{135} but it does not inhibit viral growth at concentrations attainable in human serum. In contrast, interferon (IFN)-\alpha showed an \textit{in vitro} inhibitory effect at concentrations of 1000 IU/mL.\textsuperscript{136} Interestingly, the combination of ribavirin and IFN-\beta synergistically inhibited SARS-CoV replication. The HIV protease inhibitor nelfinavir\textsuperscript{137} and the antimalarial agent chloroquine\textsuperscript{138} showed strong inhibitory activity against SARS-CoV replication. However, no cytoprotective effect was found for nelfinavir in an independent study.\textsuperscript{139,140} Structure-based virtual screening of compounds was conducted to identify novel SARS-CoV 3CL\textsuperscript{pro} inhibitors.\textsuperscript{141} The top-ranked 1468 compounds with free binding energy...
ranging from -14.0 to -17.09 kcal mol\(^{-1}\) were selected to evaluate the hydrogen bond interactions in the active site of SARS-CoV 3CL\(^{\text{pro}}\). Among them, 53 compounds were selected for their inhibitory activity towards SARS-CoV 3CL\(^{\text{pro}}\) from E-coli. Two of the compounds (186 and 187) were demonstrated to be competitive inhibitors of 3CL\(^{\text{pro}}\) with \(K_i\) values of 9.11 and 9.93 µM, respectively (Figure 34).\(^{141}\) A detailed docking simulation analyses suggested that these inhibitors could be stabilized by the formation of hydrogen-bonds with catalytic residues and the establishment of hydrophobic contacts at the opposite region of the active site. In particular, for the potent compound 187, the nitrophenyl group was likely to be very crucial in the SARS-CoV 3CL\(^{\text{pro}}\) inhibitory activity through its formation of H-bonds with Cys145 and Gly-143, as well as its hydrophobic interactions with His41 and Cys145.

Recently, the combination of virtual screening (VS) and high-throughput screening (HTS) techniques were applied to screen 41,000 compounds from structurally diverse libraries have allowed novel, non-peptidic small molecule inhibitors (188, \(IC_{50} = 13.9\) µM) and (189, \(IC_{50} = 18.2\) µM) against human SARS-CoV 3CL\(^{\text{pro}}\) to be identified (Figure 34).\(^{142}\) Since the newly identified compounds are of low molecular weight, they were examined for selectivity against three proteases, namely SARS-CoV PL\(^{\text{pro}}\) (a cysteine protease), human UCH-L1 (a cysteine protease) and Hepatitis C Virus NS3/4A (a serine protease); and two non-proteolytic enzymes, \textit{Bacillus anthracis} dihydroorotase and \textit{Streptococcus pneumoniae} PurC. Compound 189 displayed good selectivity for SARS-CoV 3CL\(^{\text{pro}}\) and did not show inhibitory activity (> 200 µM) against other five enzymes whereas compound 188 showed 20-fold selectivity against the two SARS cysteine proteases, 3CL\(^{\text{pro}}\) and PL\(^{\text{pro}}\) over other enzymes. Since low molecular weight compounds typically lack high specificity, lack of inhibition of compound 188 for other enzymes, especially the UCH-L1 cysteine protease, is particularly noteworthy.
8. Conclusion and perspectives

The emergence of SARS and the identification of a coronavirus as the causative agent of the disease astounded the coronavirus community, as it was the first definitive association of a coronavirus with a severe disease in humans. Since the first crystal structure of the SARS-CoV 3CL\textsuperscript{pro} dimer with a peptidic CMK inhibitor covalently bound was elucidated in 2003, over twenty crystal structures of the enzyme have been reported. Structure-based design and virtual screens have provided both peptidomimetic and non-peptidomimetic inhibitors with potency in the micromolar to nanomolar range. Yet, to date, there is no effective therapy for the treatment of SARS in humans, and to our knowledge, no CoV 3CL\textsuperscript{pro} inhibitor has been taken into clinical development. In this perspective, we have described the SAR for several classes of inhibitors, highlighting their structural features and binding modes. Both peptidomimetic and small molecule SARS-CoV 3CL\textsuperscript{pro} are largely based on a warhead-based design strategy. So far, only a few inhibitors have been described that exhibit good enzymatic and cellular potency, and the majority of these inhibitors have not been followed up with additional studies (such as antiviral activity or \textit{in vivo} evaluation) likely due to their unattractive structures and/or their non-ideal physiochemical properties.

The reactive warhead groups used in peptidomimetic inhibitors for SARS-CoV 3CL\textsuperscript{pro} include Michael acceptors, aldehydes, epoxy ketones, electrophilic ketones such as halomethyl ketones, and trifluromethyl ketones. Although these peptidomimetics are covalent inhibitors with the potential for toxicity, significant improvements have been made in enzymatic and cellular potency.
**Figure 35.** Profile of representative peptidic SARS-CoV 3CL\(^\text{pro}\) inhibitors highlighting reactive warhead groups (red).

Of the many peptidomimetics inhibitors described in the literature, those highlighted in Figure 35 appear to be the most promising for further optimization efforts. Compound 2 (Figure 5) is an example of an inhibitor incorporating a Michael acceptor. It was developed by Pfizer as an inhibitor of human rhinovirus 3C protease for common cold (targeted rhinovirus 3C-protease).

Although 2 was not active against SARS-CoV in cell culture, it served as a good starting point for anti-SARS drug design, leading to inhibitors 8 and 18 (see section 4.1) which are the two most potent inhibitors against SARS-CoV 3CL\(^\text{pro}\) incorporating a Michael acceptor warhead.
Specifically, compound 8 exhibited excellent cellular potency with an EC$_{50}$ value of 0.18 µM and it is a nontoxic anti-SARS agent. However, further in vivo studies for compound 8 have not been reported in the literature.

Peptidic aldehydes are promising enzymatic inhibitors, but they are unlikely to be effective as therapeutic agents due to their rapid in vivo metabolism and low oral bioavailability. In contrast, the peptide aldehyde thrombin inhibitor efegatran was well tolerated in a Phase I clinical trial.\textsuperscript{143,144} Inhibitor 45, a potent peptide aldehyde showed remarkable activity against SARS-CoV and human coronavirus (HCoV) 229E replications, reducing the viral titer by 4.7 log (at 5 µM) for SARS-CoV and 5.2 log (at 1.25 µM) for HCoV 229E. This inhibitor also displayed a stable profile in mouse, rat and human plasma (see section 4.5), and may represent a starting point for the development of an anti-SARS agent.

Inhibitor 51 is one of the potent inhibitors in the halomethyl series, exhibiting low toxicity in mice after a single ip dose at 25, 50, and 100 mg/kg, no weight loss, behavioral changes or gross pathology of major organs was observed at the tested doses (see section 4.6). The low molecular weight of 51 is a potential advantage. Since peptidyl monofluoromethyl ketones have been shown to be effective in vivo,\textsuperscript{145–147} the inhibitor 51 may be a suitable candidate for further in vivo efficacy and toxicology studies.

Numerous small molecules were also discussed in this perspective. The majority of efforts to develop non-peptide SARS-CoV 3CL$^{\text{pro}}$ inhibitors have also relied on warhead based design strategy and several of these non-peptide inhibitors achieved nanomolar potency. The most interesting inhibitors (78, 116, 119, 124, 129, 146, 160, 165 and 186) are illustrated in Figure 36. In the case of pyridyl esters, the potent mechanism based enzyme inactivator 124 (see section 5.6) achieved cell based inhibition below 10 µM in SARS-CoV infected Vero E6 cells.

Compounds 146-(R), 160 and 165 are promising examples of non-covalent SARS-CoV 3CL$^{\text{pro}}$
inhibitors of moderate molecular weights, good enzymatic and antiviral activity (see section 5.10). These inhibitors are potential starting points for the design of more potent 3CL\textsuperscript{pro} inhibitors with a non-covalent mechanism of action. However, further \textit{in vivo} studies for above mentioned small molecules have not reported so far.

**Figure 36.** Profile of representative nonpeptidic SARS-CoV 3CL\textsuperscript{pro} inhibitors highlighting reactive warhead groups (red).
Although many structural and non-structural proteins are known to be potential targets for anti-coronavirus therapy, none of them are well-conserved due to their possible role in the viral life cycle, thus limiting the potential success of wide-spectrum inhibitors. In contrast, the coronavirus 3CL$^{pro}$ is highly conserved among coronaviruses, making it an attractive target for broad-spectrum inhibitors (see SI, Table 1). The proteases share 40-60% sequence identity and 60-100% sequence similarity. Therefore, targeting SARS-CoV 3CL$^{pro}$ is an important approach for the development of anti-viral therapy that can be applied for broad viral infections. Recent reports have revealed that many SARS-CoV 3CL$^{pro}$ inhibitors showed potential activity against the recent outbreak of MERS-CoV.

A feasible and rapid advancement in the drug discovery for the development of effective chemotherapeutics against SARS-CoV might be achieved by repurposing existing and clinically approved drugs. It was recently reported that screening a library of drugs either clinically developed or with a well-defined cellular pathway from different classes of therapeutics produced a series of compounds with good activity against SARS-CoV. Drugs that inhibit CoV included neurotransmitter inhibitors, estrogen receptor antagonists, kinase signaling inhibitors, protein-processing inhibitors, inhibitors of lipid or sterol metabolism and inhibitors of DNA synthesis or pair. However, the inhibitors (peptidomimetics or non-peptidomimetics) that target other serine proteases (e.g. HCV protease, thrombin) and cysteine proteases (e.g. calpain, cathepsin K, caspases) have not been tested against 3CL$^{pro}$. For examples, ketoamides (such as A-705253 for calpain), nitriles (such as odanacatib/MK-0822 and vildagliptin/LAF237 for cathepsin K and dipeptidyl peptidase-4 (DPP4)), phenyloxymethyl ketones (such as VX-166 for caspases), fused triazole derivatives (such as sitagliptin/MK-0431 for DPP4), nonpeptides (such as apixaban/BMS-562247-01 for Factor Xa) and beta lactams for penicillin binding.
proteins such as penicillin. Therefore these structural types should be considered in future for the development of anti-SARS therapy.

$N$-Finger residues ($N$-finger) of SARS 3CL$^{pro}$ play an important role in enzyme dimerization and therefore peptides with $N$-terminal amino acid sequences may act as inhibitors of 3CL$^{pro}$ dimerization, similar HIV protease and other viral enzymes. In 2006, Wei et al. reported that $N$-terminal octapeptide N8 ($K_i$ of 2.20 mM) was the first example of inhibitor targeting the dimeric interface of SARS 3CL$^{pro}$, providing a novel strategy for drug design against SARS and other coronaviruses. However, no peptidomimetic or small molecule inhibitor has yet been reported in the literature. Although it would be a great challenge to explore new inhibitors of dimerization, with the current development of computational approaches, the structure-based design of novel inhibitors may be successful.

In conclusion, although huge efforts have been taken by both academia and pharmaceutical industries, no coronavirus protease inhibitor has yet successfully completed a preclinical development program. We hope that this perspective will be useful to medicinal chemists targeting 3CL$^{pro}$ to identify novel anti-SARS CoV inhibitors with drug-like properties, and that effective therapy for coronaviruses will be discovered.

Thanigaimalai Pillaiyar received his Master’s degree in Chemistry in 2006 from Bharathiar University, India. Prior to his doctoral study, he worked as a Research Executive at Orchid Chemicals and Pharmaceuticals Limited, India. He received his Doctoral degree in Medicinal Chemistry in 2011 under the supervision of Prof. Dr. Sang-Hun Jung at Chungnam National University, South Korea. In 2011, he won a “Japanese Society for the Promotion of Science Postdoctoral fellowship” for 2 years with Prof. Dr. Yoshio Hayashi at Tokyo University of Pharmacy and Life sciences, Japan. He was awarded an Alexander von Humboldt Postdoctoral fellowship” in 2013 for 2 years with Prof. Dr. Christa E. Müller at University of Bonn, Germany. He has been working on various therapeutic targets, focusing on infective and inflammatory diseases.

Manoj Manickam received his Ph.D. in 2010 from Bharathiar University under the supervision of Prof. Dr. K.J. Rajendra Prasad, Coimbatore, India. He continued to work as a Research Associate at Orchid Chemicals and Pharmaceuticals Ltd. Then, he moved to Chungam National University, South Korea for continuing his research. Currently, he is a Senior Research Scientist at the Department of Pharmacy and Institute of Drug Research and Development, Chungnam National University working with Professor Sang-Hun Jung.

Vigneshwaran Namasivayam is a Scientific Staff at Pharmaceutical Institute, University of Bonn, Germany (Since 2010) and involved in the field of cheminformatics, computational chemistry and molecular modelling. He gained his Master of Technology in Bioinformatics from SASTRA University, India (2004) and Doctoral degree under the supervision of Prof. Dr. Hans-Jörg Hofmann from Leipzig University, Germany (2009). He carried out his postdoctoral research at Technical University of Munich, Germany (2010). Prior to his doctoral studies in
Germany, he worked as a Research Executive (2004-2006) at Orchid Chemical and Pharmaceutical Limited, Chennai, India.

**Yoshio Hayashi** earned his Ph.D. in 1990 in the Faculty of Pharmaceutical Science, Kyoto University, under the guidance of Emeritus Prof. Haruaki Yajima and Prof. Nobutaka Fujii. After spending 2 years at Calpis Food Industry Co., Ltd. and 3 years at Nippon Steel Corporation (NSC) as a researcher, he was promoted to senior researcher at the Life Science Research Center of the NSC, where he stayed for another 8 years. In 1999, he joined Prof. Yoshiaki Kiso’s group in the Dept. of Medicinal Chemistry of Kyoto Pharmaceutical University as a lecturer, and in 2001, was appointed as an associate professor. In 2007, he moved to Tokyo University of Pharmacy and Life Sciences as a full professor. His research interests include peptide chemistry, peptidomimetics and medicinal chemistry.

**Sang-Hun Jung** received his MS degree from the College of Pharmacy of the Seoul National University in 1976. He received his Ph.D. from the Chemistry Department at the University of Houston, USA, in 1984. He served as a postdoctoral fellow at the University of Pittsburg until 1985 and as a Principle investigator of LG life Science from 1985 to 1989. He has been a professor at the College of Pharmacy, Chungnam National University, South Korea since 1989. He has served as a Department Chairman (1993-2000), Dean of the College of Pharmacy (2003-2004) and President of Institute of Drug Research and Development of Chungnam National University (2007-2009). His research interests include antimicrotubule-based anticancer agents, novel inotropes with selective activation of cardiac myosin and melanogenesis inhibitors.
